ABSTRACT*: In this paper a new method for contrast enhancement based on the discrete cosine transform is discussed and implemented. The technique converts the image into DCT domain and the DCT coefficients are modified using proposed mask then the enhanced image is reconstructed using inverse DCT. The discrete cosine transform outperforms with better image quality and highest PSNR value for noiseless gray images. We compare this approach with enhancement based on the discrete wavelet transform.*

Keywords: *Discrete cosine transform, Discrete wavelet transform.*

I. INTRODUCTION

Image Contrast Enhancement process plays an important role in enhancing image quality in which features are hardly detectable by eye. It improves the visualization of features. Basically contrast is developed due to luminance reflected by two surfaces. In satellite, medical field the contrast enhancement techniques are capable to enhance the images brightness and contrast. Histogram equalization is one the most well-known method for contrast enhancement. Such an approach generally useful for images with poor intensity distribution. By enhancing edges in image enhances the contrast. Multi scale edge enhancement approach, takes all resolution levels into account MSR softens the strongest edges and keeps the faint edges almost untouched. The strategies are different, but methods allow the user to see details which were hardly distinguishable in the original image, by reducing the ratio of strong features to faint features. The wavelet approach consists of first transforming the image using the dyadic wavelet transform. Then the two wavelet coefficients relative to the horizontal and vertical wavelet bands are modified by multipling by constant at scale and at pixel position. Finally, the enhanced image is obtained by the inverse wavelet transform from the modified wavelet coefficients. Wavelet bases present some limitations, because they are not well adapted to the detection of highly anisotropic elements, such as alignments in an image, or sheets in a cube. In DCT approach by modifying DCT coefficients of sub images can enhance the image properly.

1.1 Overview of DWT and DCT

In this paper, discrete cosine transform for enhancing the gray image has been proposed and compared with discrete wavelet transform.

1.1.1 Discrete Wavelet Transform

The wavelet approach consists of first transforming the image the two wavelet coefficients relative to the horizontal and vertical wavelet bands are modified by multiplying by constant at scale and at pixel position. Finally the enhanced image is obtained by the inverse wavelet transform from the modified wavelet coefficients. The discrete wavelet transform is based on sub band coding and easy to implement. After transforming, an image is separated into approximations and detail coefficients. Approximate coefficients are high scale, low frequency components of an image. The detail coefficients are low scale, high frequency components. Two-dimensional DWT leads to a decomposition of approximation coefficients at level j in four components: the approximation at level j + 1, and the details in three orientations (horizontal, vertical, and diagonal).The following chart describes the basic decomposition steps for images:
Figure 1: Decomposition of image

After decomposition approximate and detail coefficients are modified using properly designed scaling factor. Then using inverse transform enhanced image is reconstructed.

1.1.2 Discrete Cosine Transform

The DCT helps to separate the image into parts (or spectral sub-bands) of differing importance (with respect to the image's visual quality). As shown in Fig. The popular block-based DCT transform segments an image non overlapping block and applies DCT to each block. It gives result in three frequency sub-bands: low frequency sub-band, mid-frequency sub-band and high frequency sub-band. DCT based enhancement is based on two facts. The first fact is that much of the signal energy lies at low-frequencies sub-band which contains the most important visual parts of the image. The second fact is that high frequency components of the image and it is noise.

II. PROPOSED METHODOLOGY

In this paper, a mask has been proposed based on discrete cosine transform and discrete wavelet transform and compared for enhancing the contrast of gray images. Discrete cosine transform is applied to extract the features of an image. The DCT converts the spatial domain into frequency domain represented by its DCT coefficients. DCT coefficients are separated in higher, mid and lower frequency components. The low frequency DCT coefficients consists important information. Hence low and high frequency coefficients are modified by modifying DCT coefficients by multiplying proper scaling factor, a new enhanced gray image is obtained. For obtaining enhanced image from modified coefficients inverse DCT is used. Assume A is a gray image, A' is an enhanced image.

The following are the steps for proposed technique.
Step1: Read a gray image A.
Step2: Divide the input image into 8*8 non-overlapping sub blocks.
Step3: Apply DCT to each sub block.
Step4: Using designed mask each sub block DCT coefficients are modified.
Step5: By applying inverse DCT reconstruct the enhanced image A' from modified DCT coefficients.

III. RESULTS AND DISCUSSION

For obtaining better result different scaling factors are analyzed and best scaling factors are used to enhance the image.

IV.   VISUAL EVALUATION

Ten respondents were asked to select the images which were of the best quality according to them. From the score table it is inferred that discrete cosine transform technique is the best for enhancing noiseless gray images

Table 3: Visual Evaluation Score table

Sr.No.	Image Type	Visual Tester	
		DCT	DWT
1	Banglo.gif	6	4
2	Lenaface.gif	9	6
3	Barbara.jpg	6	7
4	Scene.gif	7	5
5	Chest.tiff	7	5
6	Moon.tiff	7	6
7	Scene1.gif	8	6
8	Mri1.tiff	6	5
9	Bird.gif	8	6
10	Ship.gif	8	6
11	Aeroplane.gif	8	5
Total Score out of 110		80	61

Some other results are as below:

**Figure 7: Discrete Cosine Transform**

Figure 8: Discrete Wavelet Transform o/p

Figure 9: Discrete Cosine Transform

Figure 10: Discrete Wavelet Transform o/p

From above results we conclude that for enhancement of gray image discrete cosine transform outperforms better than discrete wavelet transform. Using discrete cosine transform obtained highest PSNR value is 93 dB. The image quality is better than discrete wavelet transform.
